Dear Dr. Lara:

Your manuscript entitled "Complexation Studies of Nucleotides by Tetrandrine Derivatives Bearing Anthraquinone and Acridine Groups" has been successfully submitted online and is presently being given full consideration for publication in Supramolecular Chemistry.

Your manuscript ID is 

Please mention the above manuscript ID in all future correspondence or when calling the office for questions. If there are any changes in your street address or e-mail address, please log in to Manuscript Central at http://mc.manuscriptcentral.com/gsch and edit your user information as appropriate.

You can also view the status of your manuscript at any time by checking your Author Centre after logging in to http://mc.manuscriptcentral.com/gsch.

Thank you for submitting your manuscript to Supramolecular Chemistry.

Sincerely,

Supramolecular Chemistry Editorial Office

Abstract

Water soluble dicationic cyclophane-type macrocycles bearing two anthraquinone (1) or
two acridine groups (2) have been prepared by chemical modification of S,S-(+)-
tetrandrine. Complexation of nucleotide anions (mono-, di- and triphosphates) and D/L
phenylalanine by tetrandrine derivatives has been studied by UV-Visible and
fluorescence titrations in water.

Association of nucleotides to semi-synthetic hosts 1 and 2 increases with increasing
guest charge in the series AMP<sup>2+</sup> < ADP<sup>3-</sup> < ATP<sup>+</sup>. It was demonstrated for the 1- ATP
and ADP complexes that association strength is increased in the absence of salt (NaCl).

Besides, receptor 1 shows a slight preference for the complexation of UMP over
nucleotides containing A (adenine), G (guanine), C (cytosine) or T (thymine) as bases.
The major forces stabilizing the complexes result from ion pairing between the charged
groups of host and guest and from stacking or hydrophobic interactions. Receptor 1
displayed chiral recognition towards D/L phenylalanine.

Keywords: complexation, nucleotides, semisynthetic macrocycles, tetrandrine.

Dicarboxylic cyclophane-type derivatives of the macrocyclic alkaloid S,S-(+)-tetrandrine bearing two anthraquinone (1) or two acridine groups (2), displayed substantial affinity for tetraanionic nucleotides in water solution. Receptor 1 also showed enantioselectivity (K(\text{L})/K(\text{D})≈7) towards the anionic form of phenylalanine.

Introduction

Anions are important components of chemical and biological systems and for that reason different research groups have focused their investigations on anion detection and quantification.\(^1\) Nucleotides are one of the most important class of anionic molecules and because of its many biological implications, nucleotide recognition in water is an important challenge in supramolecular chemistry. Within this context several classes of synthetic and natural cationic host molecules have been studied: for example synthetic systems such as open chain polyammonium receptors,\(^2\) macrocyclic receptors such as azonia-crown and azoniacyclophanes,\(^3\) sapphyrins and porphyrin derivatives,\(^4\) polymers,\(^5\) and natural systems such as peptides.\(^6\) Among the synthetic host compounds of previous list, a considerable number of them show large binding constants towards nucleotides in water. The main strategies considered in host design are the presence of multiple cationic sites for phosphate moieties and aromatic units to simultaneously stack with the nucleotide base. However, these systems have great disadvantages: the
synthetic routes for obtaining them are most of the times sophisticated, sometimes they
show poor water solubility and frequently the ionic state of these hosts is pH-dependent.

We demonstrated previously that the use of semisynthetic macrocycles may be a
viable and easily accessible alternative to synthetic receptors. Specifically, we reported a
semisynthetic cyclophane type receptor, obtained by quaternization of nitrogen atoms of
the bisisoquinoline alkaloid S,S-(+)-tetrandrine with benzyl groups (DBT, chart 1), who
showed a moderate affinity towards phosphate-containing compounds adenosine mono-,
di- and triphosphates, with an irregular dependence on the guest charge.75

With this in mind, we expected that quaternization of both nitrogen atoms of the
alkaloid with apolar and planar units of larger surfaces than those groups employed in
DBT, i.e. anthraquinone or polycyclic arenes such as acridine, would transform it into a
dicationic receptor with affinity for negative charges of phosphate-containing
compounds such as nucleotides and with an extended cavity capable of significant
hydrophobic and π-π stacking interactions with aromatic moieties of nucleotides in
aqueous medium.

Among the nonequivalent bonds, hydrophobic and π-stacking interactions are
important ones for aromatic components. For example, intercalation of some kinds of
arenes into base pairs in DNA and RNA helices are driven by π-stacking interaction.
For that reason anthraquinone and acridine moieties are often incorporated in systems
reported in literature.8 Besides, taking into account the unique properties of
anthraquinone and acridine units (chromophore, fluorophore or electrochemical) these
make them useful as signaling units when incorporated in different structures.9

In the present study we report on the binding properties of two new water
soluble receptors derived from S,S-(+)-tetrandrine. These semi-synthetic receptors
displayed substantial affinity for tetraamionic nucleotides in water solutions comparable
to the best artificial receptors reported so far, while maintaining its chiral recognition.

Results and discussion.

Synthesis of tetrandrine derivatives
Quaternization of nitrogen atoms of S,S-(+)-tetrandrine with 2-(bromomethyl)anthraquinone or 9-(bromomethyl)acridine gave respectively compounds 1 and 2 in good yields (85-90 %). In both reactions two new chiral centers are produced at S,S-(+)-tetrandrine's nitrogens. In principle compounds 1 and 2 may be expected as a mixture of stereoisomers, however, in similar reactions with two previously reported tetrandrine derivatives,7 only one single stereoisomeric product was afforded. Accordingly, the 1H NMR spectra of macrocycles 1 and 2 show a single set of signals for all hydrogens (see Figures 1S and 2S in the Supporting Information), indicating the formation of a single stereoisomer in each case.

Solution behaviour of macrocycles
Self-association tendencies of 1 and 2 in water were studied by 1H NMR. Qualitatively a significant self-association of both compounds is manifested in broadening of NMR signals in water, but too low solubility in this solvent did not allowed us to study the process by this technique quantitatively.

The high molar extinction coefficients of receptors prompted us to monitor the self-association process by UV-vis technique. Therefore, the relations of the absorbance upon the concentration were investigated in aqueous medium at pH 7.2. For receptor 1 absorbance fitted in proportion to the concentration obeying Beer's Law, in the range $3.8 \times 10^{-6} - 1 \times 10^{-4}$ M. The same behaviour was observed for receptor 2 for concentrations in the range $3.8 \times 10^{-6} - 4.8 \times 10^{-5}$ M. These experiments allowed us to obtaining the molar extinction coefficients for maximums of absorption spectra of both compounds (see
Experimental section for values). Figures 3S and 4S in the Supporting Information contain absorption spectra of 1 and 2 at different concentrations.

On the other hand, only cyclophane 2 showed high quantum yields to being studied by fluorescence. The fluorescence spectra of 2 in water at pH 7.2 showed an emission band with a maximum at 440 nm by excitation at 350 nm in agreement with similar systems reported in literature.\textsuperscript{10} Besides, it was found that emission obeys a linear relationship with the concentration in the range 1x10\textsuperscript{-6} – 9x10\textsuperscript{-6} M. Figure 5S in the Supporting Information contain emission spectra of 2 at different concentrations.

\textbf{Complexation studies}

Dicationic cyclophanes 1 and 2, bearing anthraquinone and acridine moieties were expected as multipoint recognition hosts capable of electrostatic and \( \pi \)-stacking interactions. Thus, 1 and 2 may recognize molecules holding both aromatic and anionic moieties such as nucleotides. Chemical structures of all guests used in this study are shown in Chart 2. Also the anionic forms of D- and L-phenylalanine were included as guests to evaluate the chiral recognition ability of host 1.

\textbf{Complexation of nucleotides.} The complexation ability of 1 and 2 toward a set of nucleotides (Chart 2) in aqueous solution was evaluated by titration experiments that were monitored by UV-vis spectroscopy. All nucleotides were used as sodium salts and studies were conducted at pH 7.2, in a phosphate buffer 0.032 M.\textsuperscript{8b} At this pH nucleotides are expected to be predominantly in their fully ionized form. Addition of nucleotides to both hosts induced hypochromism in their UV-vis absorption spectra as an indication of host-guest complexation. This hypochromic effect is frequently observed with similar complexes and can be attributed to \( \pi \)-stacking coordination.\textsuperscript{11} Complex formation was observed and the absorptions recorded at 300 and 330 nm for 1 and at
350, 367 and 397 nm for 2 were plotted versus the guest concentration, at those wavelengths absorption of guest is negligible.

In the case of host 1 all data could be fitted to the 1:1 host-guest binding model since higher associations were not observed and for that reason were analyzed using the equation (1):\[ A_{\text{obs}} = \frac{(A_0 + A_r K[G]_T)}{(1 + K[G]_T)} \] (1)

Where $A_{\text{obs}}$ is the observed absorbance, $A_0$ is the absorbance of free host, $A_r$ is the maximum absorbance induced by the presence of a given guest, $[G]_T$ is the total concentration of the guest and $K$ is the binding constant.

The 1:1 stoichiometry of the species formed between 1 and nucleotides was confirmed by Job's method of continuous variation.\[13\] As an example Figure 1 shows the Job plot obtained for 1 in the presence of UMP. In this case a minimum at 0.5 is indicative of a 1:1 stoichiometry. This finding validates the use of the equation (1) for UV-vis complexation studies.

Typical titration plots for 1 and selected guests are shown in Figure 2 and the average binding constants are collected in Table 1. The following results were obtained:

Complexation strength increases with increasing guest charge: the association constant $K$ increases in the series AMP$^3$: ADP$^4$: ATP$^6$. Similar trends between guest charge and binding affinity had been previously observed in the complexation of these nucleotides with other cyclophanes. The increased affinity for nucleoside di- and triphosphates relative to monophosphates has been attributed in some instances to the electrostatic interactions displayed by the cationic host towards the multiply charged anionic.\[3b, 3c, 4c, 15\]

Triphosphate nucleotides GTP, CTP, TTP and UTP associated with 1 at comparable levels to ATP. On the other hand, binding of 1 to monophosphate
nucleotides (GMP, CMP, TMP and UMP) appeared much weakly than those to triphosphates. This fact also suggests that the electrostatic interactions (ion pairing) play a major role in host-guest association.

Complexation of receptor 1 to monophosphate nucleotides (AMP, GMP, CMP, TMP and UMP) showed no trend and it was found an unexpected higher association of 1 to UMP over the other monophosphate nucleotides, although differences in binding free energy are not very large (Table 1). This result is very interesting considering that adenine has demonstrated the strongest stacking ability in model systems.\textsuperscript{3b, 3c, 14, 15}

On the other hand, in the case of compound 2 were evaluated AMP, ADP and ATP as guests. Typical titration plots for all guests are shown in Figure 3, and the binding constants \( K \) are collected in Table 1. It is worth noting that in the case of ATP the experimental titration points do show clear deviations from the fitting curve corresponding to a 1:1 binding isotherm. For that reason, the experimental data were analyzed by using equation (2):\textsuperscript{12}

\[
A_{\text{obs}} = \frac{(A_0 + A_{11}K_{11}[G]_T + A_{12}K_{11}K_{12}[G]_T^2)}{((1 + K_{11}[G]_T + K_{11}K_{12}[G]_T^2))}
\]

(2)

Where \( A_{\text{obs}} \) is the observed absorbance, \( A_0, A_{11}, A_{12} \) are the absorbances of the free host and its 1:1 and 1:2 respective complexes, \( K_{11} \) and \( K_{12} \) are the corresponding stepwise formation constants, and \([G]_T\) is the total concentration of the guest. Thus, both complexes were considered: the 1:1 and 1:2 host-guest ratios. In addition, the 1:2 stoichiometry was confirmed by Job's method.

A simple inspection of data collected in Table 1 show that association of nucleotides to semi-synthetic host 2 increases with increasing guest charge in agreement with results found with its analog 1.
The complexation of ATP by 2 was also investigated by fluorimetric titrations. Studies were performed at pH 7.2, in a phosphate buffer (1x10^{-4} M) with 1 mM NaCl. For the fluorescence measurements the excitation wavelength was fixed at 350 nm and the emission was monitored at 437 nm. The addition of the nucleotide induced a progressive increase of the emission fluorescence spectra of 2 (a typical experiment is shown in Figure 4). It is well known that upon binding to acridines nucleobases induce a modification of the fluorescence of these dyes, with a quenching or an enhancement that depends on the acridine derivative. This effect is attributed to an overlap between the acridine and the nucleobase rings.\textsuperscript{15} The intensity emissions of 2 versus the ATP concentration were plotted and analyzed using a modified equation (2) suitable for fluorescence studies. The order of association constants $K_{11}$ and $K_{12}$ found by this study were in agreement with those for UV-vis ($K_{11} = 7015.6$ and $K_{12} = 616.6$).

The effects of varying buffer type and salt (NaCl) concentrations on AMP, ADP and ATP binding by 1 were the subject of further studies. A UV-vis titration of 1 with ATP was performed in a non-phosphate buffer solution Trizma base (0.032 M at pH 7.2 with 0.05 M NaCl). The results were in good agreement with those from the study in the phosphate buffer obtaining $K = 5306$ M$^{-1}$ for the 1-ATP complex. This further rules out any inhibition or competitive binding due to the phosphate buffer.

Furthermore, it was found that the absence of inert salt increases the binding constant. Experiments of the ATP, ADP and AMP binding by host 1 were carried out in phosphate buffer at pH 7.2 without NaCl. The absence of salt significantly altered the association constants of the 1-ATP and 1-ADP complexes which was reflected in the increased values by ca. one order, $K_{1\text{ATP}} = 63249$ M$^{-1}$ and $K_{1\text{ADP}} = 2617$ M$^{-1}$. On the other hand, the 1-AMP complex showed an unexpected insensitivity to the absence of NaCl, resulting in an association constant of same order than obtained in the presence of
0.05 NaCl (see Table 1). The fact that association constants decrease significantly when the ionic strength grows, have been demonstrated previously with many systems.\textsuperscript{2,3,5,7a}

Besides, another aspect that deserves some comment is the association strength observed for I-ATP complex in buffered solution with no salt added: taking into account purely electrostatic binding between dication I and the ATP tetraanion its K value is comparable with those found for the binding of ATP to diammonium dications of different structures.\textsuperscript{16} In contrast to our results, we can cite for example the work of Kejik \textit{et al.}\textsuperscript{16} In this work they reported a tetracationic porphyrin-alkaloid conjugated in an attempt of giving to host the sufficient positive charge to lead neutralization of ATP and at the same time the ability of establishing aromatic π-π stacking interactions with the guest. However, the calculated value of association constant for complex between mentioned tetracationic host and ATP was 64,000 M\textsuperscript{-1} being the solvent a mixture of 50:50 (v/v) methanol-HEPES buffer.

**Complexation of I with free aminoacids.** The chiral recognition ability of compound I was evaluated also by UV-titrations. These studies were conducted in a bicarbonate buffer at pH 10. At this pH, aminoacids are expected to be predominantly in their anionic form. Figure 5 illustrates the observed difference in titration curves for both enantiomers. Analysis of these plots with equation (1) allowed us to calculate binding association constants (Table 1). The results showed that binding of phenylalanine is enantioselective and the binding enantioselectivity factor can be estimated as \( K(L)/K(D) = 7 \). This preference of I by the L enantiomer is in qualitative agreement with the enantioselectivity found for its analog DBT.\textsuperscript{7b}

**Molecular modeling.** In order to rationalize the binding mode of I and 2 were performed molecular modeling of the host structures and of the I-ATP and 2-ATP complex structures. The likely structures of I and 2 were determined by molecular
mechanics simulations starting from the previously reported structure of their bisbenzylated analog. Figure 6S shows the simulated structural conformation of hosts according to which one group attached to the N(2') atom is directed out of the macrocycle cavity and the other group attached to the N(2) atom closes the cavity from the right side. This makes more probable entrance of guests from the left side; which is in agreement with previously reported DBT.

The complexation of ATP by 1 and 2 was investigated by computer modeling at semiempirical level. Results of energy minimizations were in agreement with the experimentally observed formation of stable complexes.

The estimated structure of the 1-ATP (1:1) complex calculated by a semiempirical method is presented in Figure 6. At least three oxygen atoms of phosphate moieties interact via ion pairing with N(2) ammonium centres by distances between 5.3 and 5.6 Å, sufficiently short for significant interaction. In addition, simulated complex shows interaction of the adenine base of ATP and the anthraquinone moiety attached via methyl group to the N(2') atom of tetrane, which probably contributes to the complex stability by π-stacking or hydrophobic interactions.

On the other hand, the estimated structure of the 2-ATP (1:2) complex calculated by a semiempirical method is presented in Figure 7. In this case, taking account experimental results the simulated complex showed more than expected ion pairs between oxygen atoms of phosphate moieties of both ATP molecules and N(2) or N(2') ammonium centres: at least four ionic pairs for each nitrogen with distances between 4.4 and 6.5 Å. This fact is reasonable considering that molecular modeling was made in vacuo. In addition, both anthraquinone moieties apparently contribute to the complex stability by interacting with each one adenine nucleobase.

Conclusions
The herein reported studies on the complexation of nucleotides and D/L phenylalanine by 1 and 2 semi-synthetic dicationic water soluble compounds, allow us to derive some general conclusions. First, results obtained with hosts on nucleotide complexation corroborate our hypothesis about introduction of anthraquinone and acridine moieties on tetrandrine improve interaction ability of these macrocycles with respect to previously reported DBT.

On the other hand, the fact that compounds 1 and 2 preferred triphosphate nucleotides rather than di- or monophosphate ones showed the role of electrostatic interactions in complexation. In addition a negative salt effect on these complexes also suggested that the electrostatic interactions (ion pairing) play a major role in host-guest association. However, we also observed significant contributions of stacking or hydrophobic interactions in complexation.

Among the results obtained in this paper, it is remarkable that observed association strength of cyclophanes 1 and 2 towards nucleotides demonstrates that these hosts are comparable to the best artificial receptors reported so far. Besides, host 1 displayed chiral recognition properties in the presence of phenylalanine.

**Experimental**

**General procedures and materials.** All reagents for syntheses and molecular recognition studies were purchased from commercial suppliers and used without further purification. All solutions were prepared in purified water (Barnsted Nanopure Diamond Lab Water). UV/Vis and fluorescence spectra were recorded on a Perkin Elmer Lambda 2 and Perkin Elmer LS50B respectively. A one-centimeter quartz cuvette cell holder was used. In all studies the cell holder was thermostatted at 25°C, through circulating water. NMR spectra were recorded on 400 MHz spectrometers Bruker AVANCE 400 and Varian UNITY INOVA. Chemical shifts (δ) are reported in
ppm, relative to tetramethylsilane and J values are given in hertz. Mass spectra were recorded on a high resolution Jeol MStation 700 spectrometer in FAB technique. Spectrophotometric titrations were performed on 10⁻⁶⁻¹⁰⁻² M solutions of 1 or 2 on phosphate or bicarbonate buffer, depending on the guest used, and 0.05 M NaCl. Typically aliquots of a fresh phosphate or carboxilate standard solutions of the anion were added to 1 or 2 solutions. The pH was checked at the beginning and at the end of the titration and was found constant in all cases. Guests were converted into the respective anions by adjusting the pH of their solutions in water by addition of Na₂CO₃. All spectrometric titration curves were fitted with the Microcal Origin 5.0 program. For the determination of the pKₐ values of the compound 2 spectrophotometric pH-titration was performed with 2 (3x10⁻² M) in equimolar (0.032 M) mixture of acetate, phosphate and borate buffers and 0.05 M NaCl.

**Molecular Modeling.** Molecular mechanics simulations were performed with Hypercube’s hyperchem package, using the mm+ force field as implemented in the 6.03 version of the program. The likely structures of 1 and 2 were determined by MM simulation starting from the known tetrandrine crystal structure followed by minimization in vacuo of the potential energy using a combination of conjugated gradient and Newton-Raphson algorithms using a 0.4184 kJ mol⁻¹ convergence criterion in the minimization procedure. In all cases the macrocycle structures of 1 and 2 resembled the reported X-ray structure very accurately.

Gaussian program package and the PM3 semiempirical method were used for the minimization of the binding energy and complex geometry of 1-ATP and 2-ATP. Optimized structure of the guest was placed at appropriate position maximally close to 1, which undergo a favourable geometric arrangement with interactional
complementarity for the development of electrostatic and π-stacking or hydrophobic interactions.

**Synthesis of 1 (C₆H₆N₂O₁₀Br₂)**. A solution of 2-(bromomethyl)anthraquinone (0.366 g, 1.18 mmol) in CHCl₃ (30 ml) was added to a solution of tetrandrine (0.300 g, 0.47 mmol) in CHCl₃ (80 mL), the mixture was refluxed and stirred for 24 h then the mixture was stirred for 48 h at room temperature. The solvent was evaporated and the solid product was dissolved in hot water. The small amount of solid precipitate was filtered off and the filtrated fraction was removed on a rotary evaporator with vacuum (0.535 g; yield: 90%). The compound was isolated as a yellow solid. MP: 193-198 °C. Anal. Calc. for C₃₀H₂₈N₂O₁₀Br₂: 66.12; H, 5.44; N, 2.11; found C, 61.26, H, 5.44; N, 2.11. UV absorptions λ_max(H₂O)/nm 256 (ε/dm³ mol⁻¹ cm⁻¹ 96184), 330 (9883) and λ_max(MeOH)/nm 254 (ε/dm³ mol⁻¹ cm⁻¹ 99540), 324 (9920). ¹H NMR (400 MHz; DMSO-d₆, Me₂Si): Partial assignment of signals was done by using COSY two-dimensional technique and by comparison with the spectra of tetrandrine and previously obtained N,N-dibenzylation S,S-(+)-tetrandrine in the same solvent: signals for N-CH₃ and O-CH₃ were found at δH = 2.67 (3H, s), 3.27 (3H, s), 3.51 (3H, s), 3.74 (3H, s) and 3.81 (3H, s) while signals for N-CH₂ at δH = 4.47 (1H, m), 4.77 (1H, d), 4.94 (1H, d) and 5.02 (1H, d) ppm. Signals for the ten aromatic protons of cyclophane structure are at δH = 6.20 (1H, s, H-9'), 6.51 (1H, s, H-13), 6.65 (2H, m, H13' and H-14), 6.8 (1H, s, H-6), 6.69 (2H, m, H-16' and H-16), 7.12 (1H, d, J = 7.6 Hz, H-17), 7.19 (1H, s, H-6') and 7.55 (1H, d, J = 7.5 Hz, H-17') ppm. Finally in the range 7.80-8.50 ppm the spectrum showed signals for hydrogens of the two anthraquinone units. IR ν_max/cm⁻¹: 3401.44 (C-H, conj.), 2938.86 (CH, aliphatic), 1676.46 (CO) y 1591.59 (C=C). MS m/z (FAB+): 532.61 ([I-2Br]⁻ - 2 Br⁻, 1⁺); 1145.12 ([I-2Br⁻]⁻ - Br⁻, 1⁺).
Synthesis of 2 (C₆₆H₅₂N₅O₆Br₂). 9-(bromomethyl)acridine (0.162 g, 0.579 mmol) and tetrandrine (0.147 g, 0.232 mmol) were reacted by following same procedure as that for the synthesis of compound 1. The solid precipitate isolated was washed with acetone and dried with vacuum to give 0.2355 g (85 % yield) of an orange solid. MP: 140-145 °C. Anal. Calc. for C₆₆H₅₂N₅O₆Br₂·5H₂O (1257.15) C, 63.05; H, 5.77; N, 4.45; found C, 62.65; H, 5.88; N, 4.69%. UV absorptions. \( \lambda_{\text{max}}(\text{H}_2\text{O}, \text{pH} = 7.2) / \text{nm} \) 350 sh (\( \varepsilon / \text{dm}^3 \text{ mol}^{-1} \text{ cm}^{-1} \)) 12032, 367(17458), 397(7749) and \( \lambda_{\text{max}}(\text{DMSO}) / \text{nm} \) 350 sh (\( \varepsilon / \text{dm}^3 \text{ mol}^{-1} \text{ cm}^{-1} \)) 10797, 367(15993), 397(8139). ¹H NMR (DMSO-d₆, Me₂Si, \( \delta / \text{ppm} \)): Partial assignment of signals was done in a similar way as its analog 1: signals for N-CH₃ and O-CH₃ were found at \( \delta_H = 2.23 \) (3H, s), 3.03 (3H, s), 3.12 (3H, s), 3.5 (3H, s), 3.75 (3H, s) and 3.86 (3H, s) ppm while signals for N-CH₂ at \( \delta_H = 4.34 \) (1H, s), 4.92 (1H, m), 5.62 (1H, d, \( J = 14.3 \text{ Hz} \)) and 5.76 (1H, d, \( J = 13.7 \text{ Hz} \)) ppm. Signals for the ten aromatic protons of cyclophane structure are at \( \delta_H = 6.19 \) (1H, s, H-9'), 6.35 (1H, s, H-13), 6.40 (1H, d, \( J = 6.2 \text{, H-13}' \)), 6.51 (1H, s, H-6), 6.79 (2H, m, H-14' and H-16), 6.95 (1H, d, \( J = 6.9 \text{, H-17} \)), 7.09 (1H, d, \( J = 7.2 \text{, H-16}' \)), 7.18 (1H, s, H-6') and 7.29 (1H, d, \( J = 7.2 \text{, H-17}' \)) ppm. Finally signals for hydrogens of both acridine units are in the range 7.60-9.0 ppm.

Determination of pKa values of 2. The pKa values of both acridine groups were determined by spectrophotometric titration of 2 in aqueous medium in the pH range 2-10 (see Figure 7S). The absorption spectrum of 2 shows three maximums at 367 (\( \varepsilon / 17458 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1} \text{ at pH 7.2} \)), 397 (\( \varepsilon / 7749 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1} \text{ at pH 7.2} \)) and 415 nm and one shoulder at 350 (\( \varepsilon / 12032 \text{ dm}^3 \text{ mol}^{-1} \text{ cm}^{-1} \text{ at pH 7.2} \)). For the maximum at 415 nm the absorbance increases in more acidic media and decreases significantly on increasing pH; lost of the orange color of solution is observed as a consequence of the decrement of the acridinium ion species. A typical titration curve is illustrated in Figure
7S. Titration results at four mentioned wavelengths were fitted to the equation (3) where $A_{\text{obs}}$ is the absorbance at a given wavelength and $e_{\text{HH}}$, $e_{H}$ and $e$ are the molar absorptivities of diprotonated, monoprotonated and unprotonated forms of 2 respectively. The calculated pKa values were averaged affording a pK$_a$ of 3.16 ± 0.01 for both acridine groups in agreement with similar systems reported in literature.\(^{19}\)

$$A_{\text{obs}} = \frac{(e_{\text{HH}}[H^+]^2/K_{a1} K_{a2} + e_{H}[H^+]^2/K_{a2} + e)^2}{(1+[H^+]^2/K_{a2} + [H^+]^3/K_{a1} K_{a2})} \quad (3)$$

$^a$ Only estimated an order of $10^2$ M$^{-1}$.  $^b$ Only estimated an order of $10^2$ M$^{-1}$. 
Chart 1. Chemical structures of N,N'-dibenzylated S,S-(-)-tetrandrine (DBT) and new tetrandrine derivatives with two anthraquinonylmethyl (1) or two acridinylmethyl (2) groups.
Chart 2. Chemical structures of guests employed.
Figure 1. Job plot for the complex formed between 1 and UTP: $\Delta Abs$ of 1 (the difference in absorbance of complexed and free 1) at 330 nm against its molar fraction, $X(1)$. The experiment was carried out in phosphate buffer (pH 7.2) and 0.05 M NaCl at 300 K. The total concentration of 1 + UTP was kept constant at $5 \times 10^{-4}$ M.
Figure 2. Plots of the absorbance at 330 nm of 1 with respect to the concentration of added guest, in phosphate buffer at pH 7.2 and 0.05 M NaCl. Solid lines are the fitting curves in accordance with equation (1).
Figure 3. Plots of the absorbance at 367 nm of 2 with respect to the concentration of added guest in phosphate buffer at pH 7.2 and 0.05 M NaCl. Solid lines are the fitting curves in accordance with equation (1) and dashed lines in accordance with equation (2).
Figure 4. Fluorimetric titration of 2 (1.3x10⁻⁶ M) with ATP (5.7x10⁻⁵ - 1.7x10⁻³ M) in phosphate buffer (1x10⁻⁴ M) at pH 7.2 and 1 mM NaCl. Inset: Plot of the intensity of emission at 437 nm of 2 (λₑₓc = 350 nm) with respect to the concentration of added ATP. The solid line shows the fitted curve.
Figure 5. Plots of the absorbance at 330 nm of 1 with respect to the concentration of added guest, in phosphate buffer at pH 7.2 and 0.05 M NaCl. Solid lines are the fitting curves in accordance with equation (1).
Figure 6. Simulated structure of 1-ATP complex (1:1, H-G). Hydrogens omitted.
Figure 7. Simulated structure of 2-ATP complex (1:2, H-G). Hydrogens omitted.
Figure 1S. \( ^1 \text{H} \) NMR spectrum of macrocycle 1 in DMSO-d<sub>6</sub> (see Experimental Section for signal assignments).
Figure 2S. $^1$H NMR spectrum of macrocycle 2 in DMSO-d$_6$ (see Experimental Section for signal assignments).
Figure 38. Absorption spectra of $1 \ (3.8 \times 10^{-6} - 1 \times 10^{-4} \text{ M})$ in phosphate buffer at pH 7.2 and 0.05 M NaCl.
Figure 4S. Absorption spectra of 2 (3.8x10⁻⁶ – 4.8x10⁻⁵ M) in phosphate buffer at pH 7.2 and 0.05 M NaCl.
Figure S5. Fluorescence spectra of 2 (1x10^-6 – 9x10^-6 M) in phosphate buffer at pH 7.2 and 0.05 M NaCl. The excitation wavelength was 350 nm.
Figure 6S. Simulated three-dimensional structures of tetrandrine derivatives (a) 1 and (b) 2. Hydrogens omitted.
Figure 7S. The spectrophotometric titration of 2 (3x10^{-6} M) in equimolar (0.032 M) mixture of acetate, phosphate and borate buffers and 0.05 M NaCl. Inset: plot of the absorbance of 2 at 415 nm with respect to the pH. Solid line is the fitting curve in accordance with equation (3).
